

# Package: imageData (via r-universe)

August 24, 2024

**Version** 0.1-62

**Date** 2023-08-21

**Title** Aids in Processing and Plotting Data from a Lemna-Tec Scanalyzer

**Depends** R (>= 3.1.0)

**Imports** dae, ggplot2, stats, readxl, Hmisc, GGally, RColorBrewer, reshape, grid

**Suggests** testthat, R.rsp

**VignetteBuilder** R.rsp

**Description** Note that 'imageData' has been superseded by 'growthPheno'. The package 'growthPheno' incorporates all the functionality of 'imageData' and has functionality not available in 'imageData', but some 'imageData' functions have been renamed. The 'imageData' package is no longer maintained, but is retained for legacy purposes.

**License** GPL (>= 2)

**URL** <http://chris.brien.name>

**RoxygenNote** 5.0.1

**NeedsCompilation** no

**Author** Chris Brien [aut, cre]  
(<https://orcid.org/0000-0003-0581-1817>)

**Maintainer** Chris Brien <[chris.brien@adelaide.edu.au](mailto:chris.brien@adelaide.edu.au)>

**Date/Publication** 2023-08-22 12:10:11 UTC

**Repository** <https://briencj.r-universe.dev>

**RemoteUrl** <https://github.com/cran/imageData>

**RemoteRef** HEAD

**RemoteSha** 7829148d693bf1efa43f730a8f08bc84dae95d82

## Description

Note that 'imageData' has been superseded by 'growthPheno'. The package 'growthPheno' incorporates all the functionality of 'imageData' and has functionality not available in 'imageData', but some 'imageData' functions have been renamed. The 'imageData' package is no longer maintained, but is retained for legacy purposes.

**Version:** 0.1-62

**Date:** 2023-08-21

**Index**

For an overview of the use of these functions and an example see below.

## (i) Data

[RiceRaw.dat](#) Data for an experiment to investigate a rice  
germplasm panel.

## (ii) Data frame manipulation

[designFactors](#) Adds the factors and covariates for a blocked, split-plot design.

[getDates](#) Forms a subset of 'responses' in 'data' that contains their values for the nominated times.

[importExcel](#) Imports an Excel imaging file and allows some renaming of variables.

[longitudinalPrime](#) Selects a set variables to be retained in a data frame of longitudinal data.

[twoLevelOcreate](#) Creates a data.frame formed by applying, for each response, abinary operation to the values of two different treatments.

## (iii) Plots

[anomPlot](#) Identifies anomalous individuals and produces longitudinal plots without them and with just them.

[corrPlot](#) Calculates and plots correlation matrices for a set of responses.

[imagerimesPlot](#) Plots the time within an interval versus the interval. For example, the hour of the day carts are imaged against the days after planting (or some other number of days after an event).

[longiPlot](#) Plots longitudinal data from a Lemna Tec Scanalyzer.

[probeDF](#) Compares, for a set of specified values of df, a response and the smooths of it, possibly along with growth rates calculated from the smooths.

## (iv) Calculations value-by-value

[GrowthRates](#) Calculates growth rates (AGR, PGR, RGRdiff) between pairs of values in a vector.

[WUI](#) Calculates the Water Use Index (WUI).

[anom](#) Tests if any values in a vector are anomalous in being outside specified limits.

[calcTimes](#) Calculates for a set of times, the time intervals after an origin time and the position of each with in that time.

<code>calclagged</code>	Replaces the values in a vector with the result of applying an operation to it and a lagged value.
<code>cumulate</code>	Calculates the cumulative sum, ignoring the first element if <code>exclude.1st</code> is <code>TRUE</code> .
(v) Calculations over multiple values	
<code>fitSpline</code>	Produce the fits from a natural cubic smoothing spline applied to a response in a 'data.frame'.
<code>intervalGRAverage</code>	Calculates the growth rates for a specified time interval by taking weighted averages of growth rates for times within the interval.
<code>intervalGRdiff</code>	Calculates the growth rates for a specified time interval.
<code>intervalValueCalculate</code>	Calculates a single value that is a function of an individual's values for a response over a specified time interval.
<code>intervalWUI</code>	Calculates water use indices (WUI) over a specified time interval to a data.frame.
(vi) Calculations in each split of a 'data.frame'	
<code>splitContGRdiff</code>	Adds the growth rates calculated continuously over time for subsets of a response to a 'data.frame'.
<code>splitSplines</code>	Adds the fits after fitting a natural cubic smoothing spline to subsets of a response to a 'data.frame'.
<code>splitValueCalculate</code>	Calculates a single value that is a function of an individual's values for a response.
(vii) Principal variates analysis (PVA)	
<code>intervalPVA</code>	Selects a subset of variables observed within a specified time interval using PVA.
<code>PVA</code>	Selects a subset of variables using PVA.
<code>rcontrib</code>	Computes a measure of how correlated each variable in a set is with the other variable, conditional on a nominated subset of them.

## Overview

This package can be used to carry out a full seven-step process to produce phenotypic traits from measurements made in a high-throughput phenotyping facility, such as one based on a Lemna-Tec Scanalyzer 3D system and described by Al-Tamimi et al. (2016). Otherwise, individual functions can be used to carry out parts of the process.

The basic data consists of imaging data obtained from a set of pots or carts over time. The carts are

arranged in a grid of Lanes  $\times$  Positions. There should be a unique identifier for each cart, which by default is `Snapshot.ID.Tag`, and variable giving the Days after Planting for each measurement, by default `Time.after.Planting...`. In some cases, it is expected that there will be a column labelled `Snapshot.Time.Stamp`, which reflects the time of the imaging from which a particular data value was obtained.

The full seven-step process is as follows:

1. Use `importExcel` to import the raw data from the Excel file. This step should also involve any editing of the data needed to take account of mishaps during the data collection and the need to remove faulty data (produces `raw.dat`). Generally, data can be removed by replacing only values for responses with missing values (NA) for carts whose data is to be removed, leaving the identifying information intact.
2. Use `longitudinalPrime` to select a subset of the imaging variables produced by the Lemna Tec Scanalyzer and, if the design is a blocked, split-plot design, use `designFactors` to add covariates and factors that might be used in the analysis (produces the data frame `longi.prime.dat`).
3. Add derived traits that result in a value for each observation: use `splitContGRdiff` to obtain continuous growth rates i.e. a growth rate for each time of observation, except the first; `WUI` to produce continuous Water Use Efficiency Indices (WUE) and `cumulate` to produce cumulative responses. (Produces the data frame `longi.dat`.)
4. Use `splitSplines` to fit splines to smooth the longitudinal trends in the primary traits and calculate continuous growth rates from the smoothed response (added to the data frame `longi.dat`). There are two options for calculating continuous smoothed growth rates: (i) by differencing — use `splitContGRdiff`; (ii) from the first derivatives of the splines — in `splitSplines` include 1 in the `deriv` argument, include "AGR" in `suffices.deriv` and set the RGR to say "RGR". Optionally, use `probeDF` to compare the smooths for a number of values of `df` and, if necessary, re-run `splitSplines` with a revised value of `df`.
5. Perform an exploratory examination of the unsmoothed data by using `longiPlot` to produce longitudinal plots of unsmoothed imaging traits and continuous growth rates. Also, use `longiPlot` to plot the smoothed imaging traits and continuous growth rates and `anomPlot` to check for anomalies in the data.
6. Produce cart data: traits for which there is a single value for each `Snapshot.ID.Tag` or cart. (produces the data frame `cart.dat`)
  - (a) Set up a `cart.data.frame` with the factors and covariates for a single observation from all carts. This can be done by subsetting `longi.dat` so that there is one entry for each cart.
  - (b) Use `getDates` to add traits at specific times to the `cart.data.frame`, often the first and last day of imaging for each `Snapshot.ID.Tag`. The times need to be selected so that there is one and only one observation for each cart. Also form traits, such as growth rates over the whole imaging period, based on these values
  - (c) Based on the longitudinal plots, decide on the intervals for which growth rates and WUEs are to be calculated. The growth rates for intervals are calculated from the continuous growth rates, using `intervalGRdiff`, if the continuous growth rates were calculated by differencing, or `intervalGRaverage`, if they were calculated from first derivatives. To calculate WUEs for intervals, use `intervalWUI`. The interval growth rates and WUEs are added to the `cart.data.frame`.
7. (Optional) There is also the possibility that, for experiments investigating salinity, the Shoot Ion Independent Tolerance (SIIT) index can be calculated using `twoLevelOcreate`.

**Examples**

```
## Not run:
### This example can be run because the data.frame RiceRaw.dat is available with the package
### Step 1: Import the raw data
data(RiceRaw.dat)

### Step 2: Select imaging variables and add covariates and factors (produces longi.dat)
longi.dat <- longitudinalPrime(data=RiceRaw.dat, smarthouse.lev=c("NE","NW"))

longi.dat <- designFactors(longi.dat, insertName = "xDays",
                          designfactorMethod="StandardOrder")

### Particular edits to longi.dat
longi.dat <- within(longi.dat,
  {
    Days.after.Salting <- as.numfac(Days) - 29
  })
longi.dat <- with(longi.dat, longi.dat[order(Snapshot.ID.Tag,Days), ])

### Step 3: Form derived traits that result in a value for each observation
### Set responses
responses.image <- c("Area")
responses.smooth <- paste(responses.image, "smooth", sep=".")

### Form growth rates for each observation of a subset of responses by differencing
longi.dat <- splitContGRdiff(longi.dat, responses.image,
  INDICES="Snapshot.ID.Tag",
  which.rates = c("AGR","RGR"))

### Form Area.WUE
longi.dat <- within(longi.dat,
  {
    Area.WUE <- WUI(Area.AGR*Days.diffs, Water.Loss)
  })

### Add cumulative responses
```

```

longi.dat <- within(longi.dat,
  {
    Water.Loss.Cum <- unlist(by(Water.Loss, Snapshot.ID.Tag,
                              cumulate, exclude.1st=TRUE))
    WUE.cum <- Area / Water.Loss.Cum
  })

### Step 4: Fit splines to smooth the longitudinal trends in the primary traits and
### calculate their growth rates
#'
### Smooth responses
#+
for (response in c(responses.image, "Water.Loss"))
  longi.dat <- splitSplines(longi.dat, response, x="xDays", INDICES = "Snapshot.ID.Tag",
                           df = 4, na.rm=TRUE)
longi.dat <- with(longi.dat, longi.dat[order(Snapshot.ID.Tag, xDays), ])

### Loop over smoothed responses, forming growth rates by differences
#+
responses.GR <- paste(responses.smooth, "AGR", sep=".")
longi.dat <- splitContGRdiff(longi.dat, responses.smooth,
                             INDICES="Snapshot.ID.Tag",
                             which.rates = c("AGR","RGR"))

### Finalize longi.dat
longi.dat <- with(longi.dat, longi.dat[order(Snapshot.ID.Tag, xDays), ])

### Step 5: Do exploratory plots on unsmoothed and smoothed longitudinal data
responses.longi <- c("Area","Area.AGR","Area.RGR", "Area.WUE")
responses.smooth.plot <- c("Area.smooth","Area.smooth.AGR","Area.smooth.RGR")
titles <- c("Total area (1000 pixels)",
           "Total area AGR (1000 pixels per day)", "Total area RGR (per day)",
           "Total area WUE (1000 pixels per mL)")
titles.smooth<-titles
nresp <- length(responses.longi)
limits <- list(c(0,1000), c(-50,125), c(-0.05,0.40), c(0,30))

### Plot unsmoothed profiles for all longitudinal responses
#+ "01-ProfilesAll"
klimit <- 0
for (k in 1:nresp)
{
  klimit <- klimit + 1
  longiPlot(data = longi.dat, response = responses.longi[k],
            y.title = titles[k], x="xDays+35.42857143",
            ggplotFuncs = list(geom_vline(xintercept=29, linetype="longdash", size=1),
                              scale_x_continuous(breaks=seq(28, 42, by=2)),
                              scale_y_continuous(limits=limits[[klimit]])))
}

### Plot smoothed profiles for all longitudinal responses - GRs by difference
#+ "01-SmoothedProfilesAll"

```

```

nresp.smooth <- length(responses.smooth.plot)
limits <- list(c(0,1000), c(0,100), c(0.0,0.40))
for (k in 1:nresp.smooth)
{
  longiPlot(data = longi.dat, response = responses.smooth.plot[k],
            y.title = titles.smooth[k], x="xDays+35.42857143",
            ggplotFuncs = list(geom_vline(xintercept=29, linetype="longdash", size=1),
                               scale_x_continuous(breaks=seq(28, 42, by=2)),
                               scale_y_continuous(limits=limits[[klimit]])))

  print(plt)
}

##### AGR anomalies - plot without anomalous plants followed by plot of anomalous plants
#+ "01-0254-AGRanomalies"

print(plt)
remove(tmp)

## End(Not run)

```

---

anom

*Tests if any values in a vector are anomalous in being outside specified limits*

---

## Description

Test whether any values in  $x$  are less than the value of `lower`, if it is not `NULL`, or are greater than the value of `upper`, if it is not `NULL`, or both.

**Usage**

```
anom(x, lower=NULL, upper=NULL, na.rm = TRUE)
```

**Arguments**

`x` A **vector** containing the values to be tested.

`lower` A **numeric** such that values in `x` below it are considered to be anomalous.

`upper` A **numeric** such that values in `x` above it are considered to be anomalous.

`na.rm` A **logical** indicating whether NA values should be stripped before the testing proceeds.

**Value**

A **logical** indicating whether any values have been found to be outside the limits specified by `lower` or `upper` or both.

**Author(s)**

Chris Brien

**Examples**

```
data(exampleData)
anom.val <- anom(longi.dat$Area.smooth.AGR, lower=2.5)
```

---

anomPlot	<i>Identifies anomalous individuals and produces longitudinal plots without them and with just them</i>
----------	---

---

**Description**

Uses `intervalValueCalculate` and the function `anom` to identify anomalous individuals. The user can elect to print the anomalous individuals, a longitudinal profile plot without the anomalous individuals and/or a longitudinal profile plot with only the anomalous individuals. The plots are produced using `ggplot`. The plot can be faceted so that a grid of plots is produced.

**Usage**

```
anomPlot(data, x="xDays+24.16666667", response="Area.smooth.RGR",
  individuals="Snapshot.ID.Tag",
  breaks=seq(12, 36, by=2), vertical.line=NULL,
  groupsFactor=NULL, lower=NULL, upper=NULL,
  start.time=NULL, end.time=NULL, times.factor = "Days",
  suffix.interval=NULL,
  columns.retained=c("Snapshot.ID.Tag", "Smarthouse", "Lane",
    "Position", "Treatment.1", "Genotype.ID"),
  whichPrint=c("anomalous","innerPlot","outerPlot"), na.rm=TRUE, ...)
```

**Arguments**

data	A <a href="#">data.frame</a> containing the data to be tested and plotted.
x	A <a href="#">character</a> giving the variable to be plotted on the x-axis.
response	A character specifying the response variable that is to be tested and plotted on the y-axis.
individuals	A <a href="#">character</a> giving the name(s) of the factor(s) that define the subsets of the data for which each subset corresponds to the response value for an individual.
breaks	A <a href="#">numeric</a> vector giving the breaks to be plotted on the x-axis scale.
vertical.line	A <a href="#">numeric</a> giving position on the x-axis at which a vertical line is to be drawn. If NULL, no line is drawn.
groupsFactor	A <a href="#">factor</a> giving the name of a factor that defines groups of individuals between which the test for anomalous individuals can be varied by setting values for one or more of lower, upper, start.time and end.time to be NULL, a single value or a set of values whose number equals the number of levels of groupsFactor. If NULL or only a single value is supplied, the test is the same for all individuals.
lower	A <a href="#">numeric</a> such that values in response below it are considered to be anomalous. If NULL, there is no testing for values below the lower bound.
upper	A <a href="#">numeric</a> such that values in response above it are considered to be anomalous. If NULL, there is no testing for values above the upper bound.
start.time	A <a href="#">numeric</a> giving the start of the time interval, in terms of a level of times.factor, during which testing for anomalous values is to occur. If NULL, the interval will start with the first observation.
end.time	A <a href="#">numeric</a> giving the end of the time interval, in terms of a level of times.factor, during which testing for anomalous values is to occur. If NULL, the interval will end with the last observation.
times.factor	A <a href="#">character</a> giving the name of the column in data containing the factor for times at which the data was collected. Its levels should be numeric values stored as characters.
suffix.interval	A <a href="#">character</a> giving the suffix to be appended to response to form the name of the column containing the calculated values. If it is NULL then nothing will be appended.
columns.retained	A <a href="#">character</a> giving the names of the columns in data that are to be retained in the data.frame of anomalous individuals.
whichPrint	A <a href="#">character</a> indicating what is to be printed. If anomalous is included, the columns.retained are printed for the anomalous individuals.
na.rm	A <a href="#">logical</a> indicating whether NA values should be stripped before the testing proceeds.
...	allows for arguments to be passed to <a href="#">longiPlot</a> .

**Value**

A [list](#) with three components:

1. `data`, a data frame resulting from the [merge](#) of `data` and the [logical](#) identifying whether or not an individual is anomalous;
2. `innerPlot`, an object of class `ggplot` storing the longitudinal plot of the individuals that are not anomalous;
3. `outerPlot`, an object of class `ggplot` storing the longitudinal plot of only the individuals that are anomalous.

The name of the column indicating anomalous individuals will be result of concatenating the response, `anom` and, if it is not NULL, `suffix.interval`, each separated by a full stop. The `ggplot` objects can be plotted using `print` and can be modified by adding `ggplot` functions before printing. If there are no observations to plot, NULL will be returned for the plot.

**Examples**

```
data(exampleData)
anomalous <- anomPlot(longi.dat, response="Area.smooth.AGR",
                      lower=2.5, start.time=40,
                      x = "xDays+35.42857143", vertical.line=29,
                      breaks=seq(28, 42, by=2),
                      whichPrint=c("innerPlot"),
                      y.title="Area.smooth.AGR")
```

---

calcLagged

*Replaces the values in a vector with the result of applying an operation to it and a lagged value*

---

**Description**

Replaces the values in `x` with the result of applying an operation to it and the value that is lag positions either before it or after it in `x`, depending on whether `lag` is positive or negative. For positive lag the first lag values will be NA, while for negative lag the last lag values will be NA. When operation is NULL, the values are moved lag positions down the vector.

**Usage**

```
calcLagged(x, operation = NULL, lag = 1)
```

**Arguments**

x	A <a href="#">vector</a> containing the values on which the calculations are to be made.
operation	A <a href="#">character</a> giving the operation to be performed on pairs of values in x. If operation is NULL then the values are moved lag positions down the vector.
lag	A integer specifying, for the second value in the pair to be operated on, the number positions it is ahead of or behind the current value.

**Value**

A [vector](#) containing the result of applying operation to values in x. For positive lag the first lag values will be NA, while for negative lag the last lag values will be NA.

**Author(s)**

Chris Brien

[Ops](#)

**Examples**

```
data(exampleData)
longi.dat$Days.diffs <- calcLagged(longi.dat$x$Days, operation = "-")
```

---

calcTimes	<i>Calculates for a set of times, the time intervals after an origin time and the position of each with in that time</i>
-----------	--

---

**Description**

For the column specified in imageTimes, having converted it to POSIXct if not already converted, calculates for each value the number of intervalUnits between the time and the startTime. Then the number of timePositions within the intervals is calculated for the values in imageTimes. The function difftimes is used in doing the calculations, but the results are converted to numeric. For example intervals could correspond to the number of Days after Planting and the timePositions to the hour within each day.

**Usage**

```
calcTimes(data, imageTimes = NULL, timeFormat = "%Y-%m-%d %H:%M",
           intervals = "Time.after.Planting..d.", startTime = NULL,
           intervalUnit = "days", timePositions = NULL)
```

**Arguments**

data	A <a href="#">data.frame</a> containing any columns specified by <code>imageTimes</code> , <code>intervals</code> and <code>timePositions</code> .
imageTimes	A <a href="#">character</a> giving the name of the column that contains the time that each cart was imaged. Note that in importing data into R, spaces and nonalphanumeric characters in names are converted to full stops. If <code>imageTimes</code> is NULL then no calculations are done.
timeFormat	A character giving the POSIXct format of characters containing times, in particular <code>imageTimes</code> and <code>startTime</code> . Note that if fractions of seconds are required <code>options(digits.secs)</code> must be used to set the number of decimal places and <code>timeFormat</code> must use <code>%OS</code> for seconds in <code>timeFormat</code> .
intervals	A <a href="#">character</a> giving the name of the column in <code>data</code> containing, as a <a href="#">numeric</a> or a <a href="#">factor</a> , the calculated times after <code>startTime</code> to be plotted on the x-axis. It is given as the number of <code>intervalUnits</code> between the two times. If <code>startTime</code> is NULL then <code>intervals</code> is not calculated.
startTime	A character giving the time, in the POSIXct format specified by <code>timeFormat</code> , to be subtracted from <code>imageTimes</code> to calculate intervals. For example, it might be the day of planting or treatment. If <code>startTime</code> is NULL then <code>intervals</code> is not calculated.
intervalUnit	A <a href="#">character</a> giving the name of the unit in which the values of the intervals should be expressed. It must be one of "secs", "mins", "hours" or "days".
timePositions	A <a href="#">character</a> giving the name of the column in <code>data</code> containing, as a <a href="#">numeric</a> , the value of the time position within an interval (for example, the time of imaging during the day expressed in hours plus a fraction of an hour). If <code>timePositions</code> is NULL then it is not calculated.

**Value**

A `data.frame`, being the unchanged `data` when `imageTimes` is NULL or containing either `intervals` and/or `timePositions` depending on which is not NULL.

**Author(s)**

Chris Brien

**See Also**

[as.POSIXct](#), [imagetimesPlot](#).

**Examples**

```
data(exampleData)
raw.dat <- calcTimes(data = raw.dat,
                    imageTimes = "Snapshot.Time.Stamp", timePositions = "Hour")
```

---

`corrPlot`*Calculates and plots correlation matrices for a set of responses*

---

### Description

Having calculated the correlations a heat map indicating the magnitude of the correlations is produced using `ggplot`. In this heat map, the darker the red in a cell then the closer the correlation is to -1, while the deeper the blue in the cell, then the closer the correlation is to 1. Also produced is a matrix plot of all pairwise combinations of the variables. The matrix plot contains a scatter diagram for each pair, as well as the value of the correlation coefficient. The argument `pairs.sets` can be used to restrict the pairs in the matrix plot to those combinations within each set.

### Usage

```
corrPlot(responses, data, which.plots = c("heatmap", "matrixplot"),
         title = NULL, labels = NULL, labelSize = 4,
         show.sig = FALSE, pairs.sets = NULL, ...)
```

### Arguments

<code>responses</code>	A <a href="#">character</a> giving the names of the columns in <code>data</code> containing the variables to be correlated.
<code>data</code>	A <a href="#">data.frame</a> containing the columns of variables to be correlated.
<code>which.plots</code>	A <a href="#">character</a> specifying the plots of the correlations to be produced.
<code>title</code>	Title for the plots.
<code>labels</code>	A <a href="#">character</a> specifying the labels to be used in the plots. If <code>labels</code> is <code>NULL</code> , <code>responses</code> is used for the labels.
<code>labelSize</code>	A <a href="#">numeric</a> giving the size of the labels in the <code>matrixplot</code> .
<code>show.sig</code>	A <a href="#">logical</a> indicating whether or not to give asterisks indicating significance on the plot.
<code>pairs.sets</code>	A <a href="#">list</a> each of whose components is a <a href="#">numeric</a> giving the position of the variable names in <code>responses</code> that are to be included in the set. All pairs of variables in this <code>pairs.set</code> will be included in a matrix plot.
<code>...</code>	allows passing of arguments to other functions

### Value

`NULL`.

corrPlot(responses, longi.dat, pairs.sets=list(c(1:4), c(5:7)))

## End(Not run)
```

---

cumulate	<i>Calculates the cumulative sum, ignoring the first element if exclude.1st is TRUE</i>
----------	---

---

## Description

Uses cumsum to calculate the cumulative sum, ignoring the first element if exclude.1st is TRUE.

## Usage

```
cumulate(x, exclude.1st = FALSE)
```

## Arguments

x	A <a href="#">vector</a> containing the values to be cumulated.
exclude.1st	A <a href="#">logical</a> indicating whether or not the first value of the cumulative sum is to be NA.

## Value

A [vector](#) containing the cumulative sum.

## Author(s)

Chris Brien

## See Also

[cumsum](#)

## Examples

```
data(exampleData)
Area.cum <- cumulate(longi.dat$Area)
```

---

designFactors	<i>Adds the factors and covariates for a blocked, split-plot design</i>
---------------	---

---

### Description

Add the following factors and covariates to a data frame containing imaging data from the Plant Accelerator: Zones, xZones, SHZones, ZLane, ZMainplots, Subplots and xMainPosn. It checks that the numbers of levels of the factors are consistent with the observed numbers of carts and observations.

### Usage

```
designFactors(data, insertName = NULL, designfactorMethod = "LanePosition",
             nzones = 6, nlanesperzone = 4, nmainplotsperlane = 11, nsubplotspermain = 2)
```

### Arguments

data	A <a href="#">data.frame</a> to which are to be added the design factors and covariates and which must contain the following columns: Smarthouse, Snapshot.ID.Tag, XDays, xPosn and, if designfactorMethod = "LanePosition", Lane and Position.
insertName	A <a href="#">character</a> giving the name of the column in the data.frame after which the new factors and covariates are to be inserted. If NULL, they are added after the last column.
designfactorMethod	A <a href="#">character</a> giving the method to use to obtain the columns for the design factors Zones, ZLane, Mainplots and Subplots. For LanePosition, it is assumed that (i) Lane can be divided into Zones and ZLane, each with nzones and nlanesperzone levels, respectively, and (ii) Position can be divided into Mainplots and Subplots, each with nmainplotsperlane and nmainplotsperlane levels, respectively. The factor SHZones is formed by combining Smarthouse and Zones and ZMainplots is formed by combining ZLane and Mainplots. For StandardOrder, the factors Zones, ZLane, Mainplots, Subplots are generated in standard order, with the levels of Subplots changing for every observation and the levels of subsequent changing only after all combinations of the levels of the factors to its right have been cycled through.
nzones	A <a href="#">numeric</a> giving the number of zones in a smarthouse.
nlanesperzone	A <a href="#">numeric</a> giving the number of lanes in each zone.
nmainplotsperlane	A <a href="#">numeric</a> giving the number of mainplots in each lane.
nsubplotspermain	A <a href="#">numeric</a> giving the number of subplots in a main plot.

---

 exampleData

*A small data set to use in function examples*

---

### Description

Imaging data for 20 of the plants from an experiment in a Smarthouse in the Plant Accelerator. It is used as a small example in the documentation for `imageData`.

### Usage

```
data(exampleData)
```

### Format

Four data.frames: `raw.dat` (280 rows by 33 columns), `longi.prime.dat` (280 rows by 45 columns), `longi.dat` (280 rows by 63 columns), `cart.dat` (20 rows by 14 columns).

---

 fitSpline

*Produce the fits from a natural cubic smoothing spline applied to a response in a data.frame*

---

### Description

Uses `smooth.spline` to fit a spline to all the values of response stored in `data`.

The amount of smoothing can be controlled by `df`. If `df = NULL`, the amount of smoothing is controlled by the default arguments and those you supply for `smooth.spline`. The method of Huang (2001) for correcting the fitted spline for estimation bias at the end-points will be applied if `correctBoundaries` is `TRUE`.

The derivatives of the fitted spline can also be obtained, and the Relative Growth Rate (RGR) computed using them, provided `correctBoundaries` is `FALSE`. Otherwise, growth rates can be obtained by difference using `splitContGRdiff`.

By default, `smooth.spline` will issue an error if there are not at least four distinct x-values. On the other hand, `fitSplines` issues a warning and sets all smoothed values and derivatives to NA. The handling of missing values in the observations is controlled via `na.x.action` and `na.y.action`.

### Usage

```
fitSpline(data, response, x, df=NULL, smoothing.scale = "identity",
          correctBoundaries = FALSE,
          deriv=NULL, suffices.deriv=NULL, RGR=NULL, AGR=NULL,
          na.x.action="exclude", na.y.action = "exclude", ...)
```

**Arguments**

data	A <code>data.frame</code> containing the column to be smoothed.
response	A <code>character</code> giving the name of the column in data that is to be smoothed.
x	A <code>character</code> giving the name of the column in data that contains the values of the predictor variable.
df	A <code>numeric</code> specifying the desired equivalent number of degrees of freedom of the smooth (trace of the smoother matrix). Lower values result in more smoothing. If <code>df = NULL</code> , the amount of smoothing is controlled by the default arguments for and those that you supply to <code>smooth.spline</code> .
smoothing.scale	A <code>character</code> giving the scale on which smoothing is to be performed. The two possibilities are "identity", for directly smoothing the observed response, and "logarithmic", for scaling the log-transformed response.
correctBoundaries	A <code>logical</code> indicating whether the fitted spline values are to have the method of Huang (2001) applied to them to correct for estimation bias at the end-points. Note that <code>deriv</code> must be <code>NULL</code> for <code>correctBoundaries</code> to be set to <code>TRUE</code> .
deriv	A <code>numeric</code> specifying one or more orders of derivatives that are required.
suffices.deriv	A <code>character</code> giving the characters to be appended to the names of the derivatives.
RGR	A <code>character</code> giving the character to be appended to the smoothed response to create the RGR name, but only when <code>smoothing.scale</code> is <code>identity</code> . When <code>smoothing.scale</code> is <code>identity</code> : (i) if RGR is not <code>NULL</code> <code>deriv</code> must include 1 so that the first derivative is available for calculating the RGR; (ii) if RGR is <code>NULL</code> , the RGR is not calculated from the AGR. When <code>smoothing.scale</code> is <code>logarithmic</code> , the RGR is the backtransformed first derivative and so, to obtain it, merely include 1 in <code>deriv</code> and any suffix for it in <code>suffices.deriv</code> .
AGR	A <code>character</code> giving the character to be appended to the smoothed response to create the AGR name, but only when <code>smoothing.scale</code> is <code>logarithmic</code> . When <code>smoothing.scale</code> is <code>logarithmic</code> : (i) if AGR is not <code>NULL</code> , <code>deriv</code> must include 1 so that the first derivative is available for calculating the AGR; (ii) If AGR is <code>NULL</code> , the AGR is not calculated from the RGR. When <code>smoothing.scale</code> is <code>identity</code> , the AGR is the first derivative and so, to obtain it, merely include 1 in <code>deriv</code> and any suffix for it in <code>suffices.deriv</code> .
na.x.action	A <code>character</code> string that specifies the action to be taken when values of x are NA. The possible values are <code>fail</code> , <code>exclude</code> or <code>omit</code> . For <code>exclude</code> and <code>omit</code> , predictions and derivatives will only be obtained for nonmissing values of x. The difference between these two codes is that for <code>exclude</code> the returned <code>data.frame</code> will have as many rows as data, the missing values have been incorporated.
na.y.action	A <code>character</code> string that specifies the action to be taken when values of y, or the response, are NA. The possible values are <code>fail</code> , <code>exclude</code> , <code>omit</code> , <code>allx</code> , <code>trimx</code> , <code>ltrimx</code> or <code>rtrimx</code> . For all options, except <code>fail</code> , missing values in y will be removed before smoothing. For <code>exclude</code> and <code>omit</code> , predictions and derivatives will be obtained only for nonmissing values of x that do not have missing y values. Again, the difference between these two is that, only for <code>exclude</code> will

the missing values be incorporated into the returned data.frame. For allx, predictions and derivatives will be obtained for all nonmissing x. For trimx, they will be obtained for all nonmissing x between the first and last nonmissing y values that have been ordered for x; for ltrimx and utrimx either the lower or upper missing y values, respectively, are trimmed.

... allows for arguments to be passed to smooth.spline.

### Value

A data.frame containing x and the fitted smooth. The names of the columns will be the value of x and the value of response with .smooth appended. The number of rows in the data.frame will be equal to the number of pairs that have neither a missing x or response and it will have the same order of codex as data. If deriv is not NULL, columns containing the values of the derivative(s) will be added to the data.frame; the name each of these columns will be the value of response with .smooth.dvf appended, where f is the order of the derivative, or the value of response with .smooth. and the corresponding element of suffices.deriv appended. If RGR is not NULL, the RGR is calculated as the ratio of value of the first derivative of the fitted spline and the fitted value for the spline.

*Forms a subset of responses in data that contains their values for the nominated times*

---

### Description

Forms a subset of responses in data that contains their values for the nominated times.

---

GrowthRates	<i>Calculates growth rates (AGR, PGR, RGRdiff) between pairs of values in a vector</i>
-------------	--

---

### Description

Calculates either the Absolute Growth Rate (AGR), Proportionate Growth Rate (PGR) or Relative Growth Rate (RGR) between pairs of time points, the second of which is lag positions before the first in `x`.

### Usage

```
AGRdiff(x, time.diffs, lag=1)
PGR(x, time.diffs, lag=1)
RGRdiff(x, time.diffs, lag=1)
```

### Arguments

<code>x</code>	A <a href="#">numeric</a> from which the growth rates are to be calculated.
<code>time.diffs</code>	a numeric giving the time differences between successive values in <code>x</code> .
<code>lag</code>	A integer specifying, for the second value in the pair to be operated on, the number positions it is ahead of the current value.

### Details

The `AGRdiff` is calculated as the difference between a pair of values divided by the `time.diffs`. The `PGR` is calculated as the ratio of a value to a second value which is `lag` values ahead of the first in `x` and the ratio raised to the power of the reciprocal of `time.diffs`. The `RGRdiff` is calculated as the log of the `PGR` and so is equal to the difference between the logarithms of a pair of values divided by the `time.diffs`. The differences and ratios are obtained using `calcLagged` with `lag = 1`.

### Value

A [numeric](#) containing the growth rates which is the same length as `x` and in which the first lag values NA.

```

---

imagentimesPlot	<i>Plots the position of a time within an interval against the interval for each cart</i>
-----------------	---

---

**Description**

Uses `ggplot` to produce a plot of the time position within an interval against the interval. For example, one might plot the hour of the day carts are imaged against the days after planting (or some other number of days after an event). A line is produced for each value of `groupVariable` and the colour is varied according to the value of the `colourVariable`. Each Smarthouse is plotted separately. It aids in checking whether delays occurred in imaging the plants.

**Usage**

```
imagentimesPlot(data, intervals = "Time.after.Planting..d.", timePositions = "Hour",
  groupVariable = "Snapshot.ID.Tag", colourVariable = "Lane",
  ggplotFuncs = NULL)
```

**Arguments**

<code>data</code>	A <a href="#">data.frame</a> containing any columns specified by <code>intervals</code> , <code>timePositions</code> , <code>groupVariable</code> and <code>colourVariable</code> .
<code>intervals</code>	A <a href="#">character</a> giving the name of the column in <code>data</code> containing, as a <a href="#">numeric</a> or a <a href="#">factor</a> , the calculated times to be plotted on the x-axis. For example, it could be the days after planting or treatment.
<code>timePositions</code>	A <a href="#">character</a> giving the name of the column in <code>data</code> containing, as a <a href="#">numeric</a> , the value of the time position within an interval (for example, the time of imaging during the day expressed in hours plus a fraction of an hour).
<code>groupVariable</code>	A <a href="#">character</a> giving the name of the column in <code>data</code> containing the variable to be used to group the plotting.
<code>colourVariable</code>	A <a href="#">character</a> giving the name of the column in <code>data</code> containing the variable to be used to colour the plotting.
<code>ggplotFuncs</code>	A <a href="#">list</a> , each element of which contains the results of evaluating a <a href="#">ggplot</a> function. It is created by calling the <a href="#">list</a> function with a <a href="#">ggplot</a> function call for each element.

**Value**

An object of class "ggplot", which can be plotted using `print`.

```
data(exampleData)
library(ggplot2)
longi.dat <- calcTimes(longi.dat, imageTimes = "Snapshot.Time.Stamp",
                      timePositions = "Hour")
imagetimesPlot(data = longi.dat, intervals = "Days", timePositions = "Hour",
               ggplotFuncs=list(scale_colour_gradient(low="grey20", high="black"),
                               geom_line(aes(group=Snapshot.ID.Tag, colour=Lane))))
```

---

importExcel

---

*Imports an Excel imaging file and allows some renaming of variables*

---

**Description**

Uses `readxl` to import a sheet of imaging data produced by the Lemna Tec Scanalyzer. Basically, the data consists of imaging data obtained from a set of pots or carts over time. There should be a column, which by default is called `Snapshot.ID.Tag`, containing a unique identifier for each cart and a column, which by default is labelled `Snapshot.Time.Stamp`, containing the time of imaging for each observation in a row of the sheet. Also, if `startTime` is not `NULL`, `calcTimes` is called to calculate, or recalculate if already present, `timeAfterStart` from `imageTimes` by subtracting a supplied `startTime`.

Using `cameraType`, `keepCameraType`, `labsCamerasViews` and `prefix2suffix`, some flexibility is provided for renaming the columns with imaging data. For example, if the column names are prefixed with `'RGB_SV1'`, `'RGB_SV2'` or `'RGB_TV'`, the `'RGB_'` can be removed and the `'SV1'`, `'SV2'` or `'TV'` become suffices.

**Usage**

```
importExcel(file, sheet="raw data", sep = ",",
            cartId = "Snapshot.ID.Tag",
            imageTimes = "Snapshot.Time.Stamp",
            timeAfterStart = "Time.after.Planting..d.",
            cameraType = "RGB", keepCameraType = FALSE,
            labsCamerasViews = NULL, prefix2suffix = TRUE,
            startTime = NULL,
            timeFormat = "%Y-%m-%d %H:%M",
            imagetimesPlot = TRUE, ...)
```

**Arguments**

file	A <a href="#">character</a> giving the path and name of the file containing the data.
sheet	A <a href="#">character</a> giving the name of the sheet containing the data, that must include columns whose names are as specified by <code>cartId</code> , which uniquely indexes the carts in the experiment, and <code>imageTimes</code> , which reflects the time of the imaging from which a particular data value was obtained. It is also assumed that a column whose name is specified by <code>timeAfterStart</code> is in the sheet or that it will be calculated from <code>imageTimes</code> using the value of <code>startTime</code> supplied in the function call.
sep	A <a href="#">character</a> giving the separator used in a csv file.
cartId	A <a href="#">character</a> giving the name of the column that contains the unique Id for each cart. Note that in importing data into R, spaces and nonalphanumeric characters in names are converted to full stops.
imageTimes	A <a href="#">character</a> giving the name of the column that contains the time that each cart was imaged. Note that in importing data into R, spaces and nonalphanumeric characters in names are converted to full stops.
timeAfterStart	A <a href="#">character</a> giving the name of the column that contains or is to contain the difference between <code>imageTimes</code> and <code>startTime</code> . The function <code>calcTimes</code> is called to calculate the differences. For example, it might contain the number of days after planting. Note that in importing data into R, spaces and nonalphanumeric characters in names are converted to full stops.
cameraType	A <a href="#">character</a> string nominating the abbreviation used for the cameraType. A warning will be given if no variable names include this cameraType.
keepCameraType	A logical specifying whether to retain the cameraType in the variables names. It will be the start of the prefix or suffix and separated from the remainder of the prefix or suffix by an underscore ( <code>_</code> ).
labsCamerasViews	A named <a href="#">character</a> whose elements are new labels for the camera-view combinations and the name of each element is the old label for the camera-view combination in the data being imported. If <code>labsCamerasViews</code> is NULL, all column names beginning with <code>cameraType</code> are classed as imaging variables and the unique prefixes amongst them determined. If no imaging variables are found then no changes are made. Note that if you want to include a recognisable cameraType in a camera-view label, it should be at the start of the label in <code>labsCamerasViews</code> and separated from the rest of the label by an underscore ( <code>_</code> ).
prefix2suffix	A logical specifying whether the variables names with prefixed camera-view labels are to have those prefixes transferred to become suffices. The prefix is assumed to be all the characters up to the first full stop ( <code>.</code> ) in the variable name and must contain <code>cameraType</code> to be moved. It is generally assumed that the characters up to the first underscore ( <code>_</code> ) are the camera type and this is removed if <code>keepCameraType</code> is FALSE. If there is no underscore ( <code>_</code> ), the whole prefix is moved. If <code>labsCamerasViews</code> is NULL, all column names beginning with <code>cameraType</code> are classed as imaging variables and the unique prefixes amongst them determined. If no imaging variables are found then no changes are made.

startTime	A character giving the time of planting, in the POSIXct format timeFormat, to be subtracted from imageTimes in recalculating timeAfterStart. If startTime is NULL then timeAfterStart is not recalculated.
timeFormat	A character giving the POSIXct format of characters containing times, in particular imageTimes and startTime.
imagetimesPlot	A logical indicating whether a plot of the imaging times against the recalculated Time.After.Planting... It aids in checking Time.After.Planting... and what occurred in imaging the plants.
...	allows for arguments to be passed to <code>imagetimesPlot</code> . However, if intervals is passed an error will occur; use <code>timeAfterStart</code> instead.

**Value**

A `data.frame` containing the data.

**Author(s)**

Chris Brien

**See Also**

`as.POSIXct`, `calcTimes`, `imagetimesPlot`

**Examples**

```
## Not run:
raw.0169.dat <- importExcel(file = "0169 analysis_20140603.xlsx",
                           startTime = "2013-05-23 8:00 AM")

camview.labels <- c("SF0", "SL0", "SU0", "TV0")
names(camview.labels) <- c("RGB_Side_Far_0", "RGB_Side_Lower_0",
                          "RGB_Side_Upper_0", "RGB_TV_0")
raw.19.dat <- suppressWarnings(importExcel(file = "../data/raw19datarow.csv",
                                          cartId = "Snapshot.ID.Tags",
                                          startTime = "06/10/2017 0:00 AM",
                                          timeFormat = "%d/%m/%Y %H:M",
                                          labsCamerasViews = camview.labels,
                                          imagetimesPlot = FALSE))

## End(Not run)
```

---

intervalGRAverage	<i>Calculates the growth rates for a specified time interval by taking weighted averages of growth rates for times within the interval</i>
-------------------	--

---

## Description

Using previously calculated growth rates over time, calculates the Absolute Growth Rates for a specified interval using the weighted averages of AGRs for each time point in the interval (AGR) and the Relative Growth Rates for a specified interval using the weighted geometric means of RGRs for each time point in the interval (RGR).

## Usage

```
intervalGRAverage(responses, individuals = "Snapshot.ID.Tag",
                  which.rates = c("AGR","RGR"), suffices.rates=c("AGR","RGR"),
                  start.time, end.time, times.factor = "Days", suffix.interval,
                  data, sep=".", na.rm=TRUE)
```

## Arguments

responses	A <a href="#">character</a> giving the names of the responses for which there are columns in data that contain the growth rates that are to be averaged. The names of the growth rates should have either AGR or RGR appended to the responses names.
individuals	A <a href="#">character</a> giving the name(s) of the factor(s) that define the subsets of the data for which each subset corresponds to the responses for an individual.
which.rates	A <a href="#">character</a> giving the growth rates that are to be averaged to obtain growth rates for an interval. It should be a combination "AGR" and "RGR".
suffices.rates	A <a href="#">character</a> giving the suffices to be appended to response to form the names of the columns containing the calculated the growth rates and in which growth rates are to be stored. Their elements will be matched with those of which.rates.
start.time	A <a href="#">numeric</a> giving the times, in terms of levels of times.factor, that will give a single value for each Snapshot.ID.Tag and that will be taken as the observation at the start of the interval for which the growth rate is to be calculated.
end.time	A <a href="#">numeric</a> giving the times, in terms of levels of times.factor, that will give a single value for each Snapshot.ID.Tag and that will be taken as the observation at the end of the interval for which the growth rate is to be calculated.
times.factor	A <a href="#">character</a> giving the name of the column in data containing the factor for times at which the data was collected. Its levels will be used in calculating growth rates and should be numeric values stored as characters.
suffix.interval	A <a href="#">character</a> giving the suffix to be appended to response.suffices.rates to form the names of the columns containing the calculated the growth rates.
data	A <a href="#">data.frame</a> containing the columns from which the growth rates are to be calculated.
sep	A <a href="#">character</a> giving the separator to use when the levels of individuals are combined. This is needed to avoid using a <a href="#">character</a> that occurs in a factor to delimit levels when the levels of individuals are combined to identify subsets.
na.rm	A <a href="#">logical</a> indicating whether NA values should be stripped before the calculation of weighted means proceeds.

## Details

The AGR for an interval is calculated as the weighted mean of the AGRs for times within the interval. The RGR is calculated as the weighted geometric mean of the RGRs for times within the interval; in fact the exponential is taken of the weighted means of the logs of the RGRs. The weights are obtained from the `times.factor`. They are taken as the sum of half the time subintervals before and after each time, except for the end points; the end points are taken to be the subintervals at the start and end of the interval.

## Value

A `data.frame` with the growth rates. The name of each column is the concatenation of (i) one of responses, (ii) one of AGR, PGR or RGR, or the appropriate element of `suffices.rates`, and (iii) `suffix.interval`, the three components being separated by full stops.

data(exampleData)
longi.dat <- splitSplines(longi.dat, response="Area", x="xDays",
  INDICES = "Snapshot.ID.Tag",
  df = 4, deriv=1, suffices.deriv="AGRdv", RGR="RGRdv")
Area.smooth.GR <- intervalGRaverage("Area.smooth", which.rates = c("AGR","RGR"),
  suffices.rates = c("AGRdv","RGRdv"),
  start.time = 31, end.time = 35,
  suffix.interval = "31to35",
  data = longi.dat)
```

---

intervalGRdiff

*Calculates the growth rates for a specified time interval*

---

## Description

Using the values of the responses, calculates the specified combination of the Absolute Growth Rates using differences (AGR), the Proportionate Growth Rates (PGR) and Relative Growth Rates using log differences (RGR) between two nominated time points.

## Usage

```
intervalGRdiff(responses, individuals = "Snapshot.ID.Tag",
  which.rates = c("AGR","PGR","RGR"), suffices.rates=NULL,
  times.factor = "Days", start.times, end.times, suffix.interval,
  data)
```

**Arguments**

responses	A <b>character</b> giving the names of the columns in data from which the growth rates are to be calculated.
individuals	A <b>character</b> giving the name(s) of the factor(s) that define the subsets of the data for which each subset corresponds to the responses for an individual.
which.rates	A <b>character</b> giving the growth rates that are to be calculated. It should be a combination "AGR", "PGR" and "RGR".
suffices.rates	A <b>character</b> giving the characters to be appended to the names of the responses in constructing the names of the columns containing the calculated growth rates. The order of the suffices in suffices.rates should correspond to the order of the elements of which.rates.
times.factor	A <b>character</b> giving the name of the column in data containing the factor for times at which the data was collected. Its levels will be used in calculating growth rates and should be numeric values stored as characters.
start.times	A <b>numeric</b> giving the times, in terms of levels of times.factor, that will give a single value for each Snapshot.ID.Tag and that will be taken as the observation at the start of the interval for which the growth rate is to be calculated.
end.times	A <b>numeric</b> giving the times, in terms of levels of times.factor, that will give a single value for each Snapshot.ID.Tag and that will be taken as the observation at the end of the interval for which the growth rate is to be calculated.
suffix.interval	A <b>character</b> giving the suffix to be appended to response to form the names of the columns containing the calculated the growth rates.
data	A <b>data.frame</b> containing the column from which the growth rates are to be calculated.

**Details**

The AGR is calculated as the difference between the values of response at the end.times and start.times divided by the difference between end.times and start.times. The PGR is calculated as the ratio of response at the end.times to that at start.times and the ratio raised to the power of the reciprocal of the difference between end.times and start.times. The RGR is calculated as the log of the PGR and so is equal to the difference between the logarithms of response at the end.times and start.times divided by the difference between end.times and start.times.

**Value**

A **data.frame** with the growth rates. The name of each column is the concatenation of (i) one of responses, (ii) one of AGR, PGR or RGR, or the appropriate element of suffices.rates, and (iii) suffix.interval, the three components being separated by full stops.

                                start.times = 31, end.times = 35,
                                suffix.interval = "31to35",
                                data = longi.dat)
```

---

intervalPVA	<i>Selects a subset of variables observed within a specified time interval using Principal Variable Analysis (PVA)</i>
-------------	--

---

**Description**

Principal Variable Analysis (PVA) (Cummings, 2007) selects a subset from a set of the variables such that the variables in the subset are as uncorrelated as possible, in an effort to ensure that all aspects of the variation in the data are covered. Here, all observations in a specified time interval are used for calculation the correlations on which the selection is based.

**Usage**

```
intervalPVA(responses, data, times.factor = "Days", start.time, end.time,
            nvselect = NULL, p.variance = 1, include = NULL,
            plot = TRUE, ...)
```

**Arguments**

responses	A <a href="#">character</a> giving the names of the columns in data from which the variables are to be selected.
data	A <a href="#">data.frame</a> containing the columns of variables from which the selection is to be made.
times.factor	A <a href="#">character</a> giving the name of the column in data containing the factor for times at which the data was collected. Its levels will be used to identify the subset and should be numeric values stored as characters.
start.time	A numeric giving the time, in terms of a level of times.factor, at which the time interval begins; observations at this time and up to and including end.time will be included.
end.time	A numeric giving the time, in terms of levels of times.factor, at the end of the interval; observations after this time will not be included.
nvselect	A <a href="#">numeric</a> specifying the number of variables to be selected, which includes those listed in include. If nvselect = 1, as many variables are selected as is need to satisfy p.variance.

p.variance	A <a href="#">numeric</a> specifying the minimum proportion of the variance that the selected variables must account for,
include	A <a href="#">character</a> giving the names of the columns in data for the variables whose selection is mandatory.
plot	A <a href="#">logical</a> indicating whether a plot of the cumulative proportion of the variance explained is to be produced.
...	allows passing of arguments to other functions.

### Details

The variable that is most correlated with the other variables is selected first for inclusion. The partial correlation for each of the remaining variables, given the first selected variable, is calculated and the most correlated of these variables is selected for inclusion next. Then the partial correlations are adjusted for the second included variables. This process is repeated until the specified criteria have been satisfied. The possibilities are to:

1. the default (`nvarselect = NULL` and `p.variance = 1`) select all variables in increasing order of amount of information they provide;
2. select exactly `nvarselect` variables;
3. select just enough variables, up to a maximum of `nvarselect` variables, to explain at least `p.variance*100` per cent of the total variance.

### Value

A [data.frame](#) giving the results of the variable selection. It will contain the columns `Variable`, `Selected`, `h.partial`, `Added.Proprn` and `Cumulative.Proprn`.

### Examples

```
data(exampleData)
responses <- c("Area", "Area.SV", "Area.TV", "Image.Biomass", "Max.Height", "Centre.Mass",
              "Density", "Compactness.TV", "Compactness.SV")
results <- intervalPVA(responses, longi.dat,
                      start.time = "31", end.time = "31",
                      p.variance=0.9, plot = FALSE)
```

---

 intervalValueCalculate

*Calculates a single value that is a function of an individual's values for a response over a specified time interval*

---

## Description

Splits the values of a response into subsets corresponding individuals and applies a function that calculates a single value from each individual's observations during a specified time interval. It includes the ability to calculate the observation that corresponds to the calculated value of the function.

## Usage

```
intervalValueCalculate(response, weights=NULL, individuals = "Snapshot.ID.Tag",
  FUN = "max", which.obs = FALSE, which.levels = NULL,
  start.time=NULL, end.time=NULL, times.factor = "Days",
  suffix.interval=NULL, data, sep=".", na.rm=TRUE, ...)
```

## Arguments

response	A <a href="#">character</a> giving the name of the column in data from which the values of FUN are to be calculated.
weights	A <a href="#">character</a> giving the name of the column in data containing the weights to be supplied as w to FUN.
individuals	A <a href="#">character</a> giving the name(s) of the factor(s) that define the subsets of the data for which each subset corresponds to the response value for an individual.
FUN	A <a href="#">character</a> giving the name of the function that calculates the value for each subset.
which.obs	A <a href="#">logical</a> indicating whether or not to determine the observation corresponding to the value of the function, instead of the value of the function itself.
which.levels	A <a href="#">character</a> giving the name of the <a href="#">factor</a> whose levels are to be identified as the level of the observation whose value matches the value of the function.
start.time	A <a href="#">numeric</a> giving the times, in terms of levels of times.factor, that will give a single value for each Snapshot.ID.Tag and that will be taken as the observation at the start of the interval for which the growth rate is to be calculated. If start.time is NULL, the interval will start with the first observation.
end.time	A <a href="#">numeric</a> giving the times, in terms of levels of times.factor, that will give a single value for each Snapshot.ID.Tag and that will be taken as the observation at the end of the interval for which the growth rate is to be calculated. If end.time is NULL, the interval will end with the last observation.
times.factor	A <a href="#">character</a> giving the name of the column in data containing the factor for times at which the data was collected. Its levels should be numeric values stored as characters.

suffix.interval	A <a href="#">character</a> giving the suffix to be appended to response to form the name of the column containing the calculated values. If it is NULL then nothing will be appended.
data	A <a href="#">data.frame</a> containing the column from which the function is to be calculated.
na.rm	A <a href="#">logical</a> indicating whether NA values should be stripped before the calculation proceeds.
sep	A <a href="#">character</a> giving the separator to use when the levels of individuals are combined. This is needed to avoid using a <a href="#">character</a> that occurs in a factor to delimit levels when the levels of individuals are combined to identify subsets.
...	allows for arguments to be passed to FUN.

**Value**

A [data.frame](#), with the same number of rows as there are individuals, containing a column for the individuals, a column with the values of the function for the individuals, and a column with the values of the times.factor. The name of the column with the values of the function will be result of concatenating the response, FUN and, if it is not NULL, suffix.interval, each separated by a full stop.

**Author(s)**

Chris Brien

data(exampleData)
Area.smooth.max <- intervalValueCalculate("Area.smooth",
                                          start.time = 31, end.time = 35,
                                          suffix.interval = "31to35",
                                          data = longi.dat)
```

---

intervalWUI

*Calculates water use indices (WUI) over a specified time interval to a data.frame*

---

**Description**

Calculates the Water Use Index (WUI) between two time points for a set of responses.

**Usage**

```
intervalWUI(responses, water.use = "Water.Use",
            individuals = "Snapshot.ID.Tag", times.factor = "Days",
            start.times, end.times, suffix.interval = NULL,
            data, include.total.water = FALSE, na.rm = FALSE)
```

**Arguments**

responses	A <a href="#">character</a> giving the names of the columns in data from which the growth rates are to be calculated.
water.use	A <a href="#">character</a> giving the names of the column in data which contains the water use values.
individuals	A <a href="#">character</a> giving the name(s) of the factor(s) that define the subsets of the data for which each subset corresponds to the responses for an individual.
times.factor	A <a href="#">character</a> giving the name of the column in data containing the factor for times at which the data was collected. Its levels will be used in identifying the intervals and should be numeric values stored as characters.
start.times	A numeric giving the times, in terms of levels of <code>times.factor</code> , that will give a single value for each <code>Snapshot.ID.Tag</code> and that will be taken as the observation at the start of the interval for which the growth rate is to be calculated.
end.times	A numeric giving the times, in terms of levels of <code>times.factor</code> , that will give a single value for each <code>Snapshot.ID.Tag</code> and that will be taken as the observation at the end of the interval for which the growth rate is to be calculated.
suffix.interval	A <a href="#">character</a> giving the suffix to be appended to response to form the names of the columns containing the calculated the growth rates.
data	A <a href="#">data.frame</a> containing the column from which the growth rates are to be calculated.
include.total.water	A <a href="#">logical</a> indicating whether or not to include a column in the results for the total of <code>water.use</code> for the interval for each individual.
na.rm	A <a href="#">logical</a> indicating whether NA values should be stripped before the calculation proceeds.

**Details**

The WUI is calculated as the difference between the values of a response at the `end.times` and `start.times` divided by the sum of the water use after `start.times` until `end.times`. Thus, the water use up to `start.times` is not included.

**Value**

A [data.frame](#) containing the WUIs, the name of each column being the concatenation of one of `responses`, `WUI` and, if not `NULL`, `suffix.interval`, the three components being separated by a full stop. If the total water is to be included, the name of the column will be the concatenation of `water.use`, `Total` and the suffix, each separated by a full stop(' ').

**Author(s)**

Chris Brien

```
data(exampleData)
Area.smooth.WUI <- intervalWUI("Area", water.use = "Water.Loss",
                              start.times = 31, end.times = 35,
                              suffix = "31to35",
                              data = longi.dat, include.total.water = TRUE)
```

longiPlot

*Plots longitudinal data from a Lemna Tec Scanalyzer***Description**

Produce profile or longitudinal plots of the data from a Lemna Tec Scanalyzer using ggplot. A line is drawn for the data for each Snapshot.ID.Tag and the plot can be faceted so that a grid of plots is produced.

**Usage**

```
longiPlot(data, x = "xDays+44.5", response = "Area", individuals="Snapshot.ID.Tag",
          x.title = "Days", y.title = "Area (1000 pixels)", title = NULL,
          facet.x = "Treatment.1", facet.y = "Smarthouse", labeller = NULL,
          colour = "black", colour.column=NULL, colour.values=NULL,
          alpha = 0.1, ggplotFuncs = NULL, printPlot = TRUE)
```

**Arguments**

data	A <a href="#">data.frame</a> containing the data to be plotted.
x	A <a href="#">character</a> giving the variable to be plotted on the x-axis.
response	A character specifying the response variable that is to be plotted on the y-axis.
individuals	A <a href="#">character</a> giving the name(s) of the <a href="#">factor</a> (s) that define the subsets of the data for which each subset corresponds to the response values for an individual.
x.title	Title for the x-axis.
y.title	Title for the y-axis.
title	Title for the plot.
facet.x	A <a href="#">data.frame</a> giving the variable to be used to form subsets to be plotted in separate columns of plots. Use "." if a split into columns is not wanted.

facet.y	A <a href="#">data.frame</a> giving the variable to be used to form subsets to be plotted in separate rows of plots. Use "." if a split into columns is not wanted.
labeller	A <a href="#">ggplot function</a> for labelling the facets of a plot produced using the <a href="#">ggplot</a> function. For more information see <a href="#">ggplot</a> .
colour	A <a href="#">character</a> specifying a single colour to use in drawing the lines for the profiles. If colouring according to the values of a variable is required then use <code>colour.column</code> .
colour.column	A <a href="#">character</a> giving the name of a column in data over whose values the colours of the lines are to be varied. The colours can be specified using <code>colour.values</code> .
colour.values	A <a href="#">character</a> vector specifying the values of the colours to use in drawing the lines for the profiles. If this is a named vector, then the values will be matched based on the names. If unnamed, values will be matched in order (usually alphabetical) with the limits of the scale.
alpha	A <a href="#">numeric</a> specifying the degrees of transparency to be used in plotting. It is a ratio in which the denominator specifies the number of points (or line) that must be overplotted to give a solid cover.
ggplotFuncs	A <a href="#">list</a> , each element of which contains the results of evaluating a <a href="#">ggplot</a> function. It is created by calling the <a href="#">list</a> function with a <a href="#">ggplot</a> function call for each element.
printPlot	A <a href="#">logical</a> indicating whether or not to print the plot.

**Value**

An object of class "[ggplot](#)", which can be plotted using `print`.

                  ggplot2::scale_x_continuous(breaks=seq(28, 42, by=2)),
                  ggplot2::scale_y_continuous(limits=c(0,750)))
```

---

longitudinalPrime	<i>Selects a set variables to be retained in a data frame of longitudinal data</i>
-------------------	--

---

## Description

Forms the prime traits by selecting a subset of the traits in a data.frame of imaging data produced by the Lemna Tec Scanalyzer. The imaging traits to be retained are specified using the traits and labsCamerasViews arguments. Some imaging traits are divided by 10000 to convert them from pixels to kilopixels. Also added are factors and explanatory variates that might be of use in an analysis.

## Usage

```
longitudinalPrime(data, cartId = "Snapshot.ID.Tag",
                  imageTimes = "Snapshot.Time.Stamp",
                  timeAfterStart = "Time.after.Planting.d.",
                  idcolumns = c("Genotype.ID", "Treatment.1"),
                  traits = list(all = c("Area",
                                       "Boundary.Points.To.Area.Ratio",
                                       "Caliper.Length", "Compactness",
                                       "Convex.Hull.Area"),
                              side = c("Center.Of.Mass.Y",
                                       "Max.Dist.Above.Horizon.Line")),
                  labsCamerasViews = list(all = c("SV1", "SV2", "TV"),
                                           side = c("SV1", "SV2")),
                  smarthouse.lev = NULL,
                  calcWaterLoss = TRUE, pixelsPERcm)
```

## Arguments

data	A <a href="#">data.frame</a> containing the columns specified by cartId, imageTimes, timeAfterStart, idcolumns, traits and cameras along with the following columns: Smarthouse, Lane, Position, Weight.Before, Weight.After, Water.Amount, Projected.Shoot.Area..pixels. The defaults for the arguments to longitudinalPrime requires a <a href="#">data.frame</a> containing the following columns, although not necessarily in the order given here: Smarthouse, Lane, Position, Weight.Before, Weight.After, Water.Amount, Projected.Shoot.Area..pixels., Area.SV1, Area.SV2, Area.TV, Boundary.Points.To.Area.Ratio.SV1, Boundary.Points.To.Area.Ratio.SV2, Boundary.Points.To.Area.Ratio.TV, Caliper.Length.SV1,
------	--

	Caliper.Length.SV2, Caliper.Length.TV, Compactness.SV1, Compactness.SV2, Compactness.TV, Convex.Hull.Area.SV1, Convex.Hull.Area.SV2, Convex.Hull.Area.TV, Center.Of.Mass.Y.SV1, Center.Of.Mass.Y.SV2, Max.Dist.Above.Horizon.Line.SV1, Max.Dist.Above.Horizon.Line.SV2.
cartId	A <a href="#">character</a> giving the name of the column that contains the unique Id for each cart.
imageTimes	A <a href="#">character</a> giving the name of the column that contains the time that each cart was imaged.
timeAfterStart	A <a href="#">character</a> giving the name of the column that contains the time after some nominated starting time e.g. the number of days after planting.
idcolumns	A <a href="#">character</a> vector giving the names of the columns that identify differences between the plants or carts e.g. Genotype.ID, Treatment.1, Treatment.2.
traits	A <a href="#">character</a> or a <a href="#">list</a> whose components are <a href="#">characters</a> . Each <a href="#">character</a> gives the names of the columns for imaging traits whose values are required for each of the camera-view combinations given in the corresponding <a href="#">list</a> component of labsCamerasViews. If labsCamerasViews or a component of labsCamerasViews is NULL, then the contents of traits or the corresponding component of traits are merely treated as the names of columns to be retained.
labsCamerasViews	A <a href="#">character</a> or a <a href="#">list</a> whose components are <a href="#">characters</a> . Each <a href="#">character</a> gives the labels of the camera-view combinations for which is required values of each of the imaging traits in the corresponding <a href="#">character</a> of traits. It is assumed that the camera-view labels are appended to the trait names and separated from the trait names by a full stop (.). If labsCamerasViews or a component of labsCamerasViews is NULL, then the contents of the traits or the corresponding component of traits are merely treated as the names of columns to be retained.
smarthouse.lev	A <a href="#">character</a> vector giving the levels to use for the Smarthouse factor. If NULL then the unique values in Smarthouse will be used.
calcWaterLoss	A <a href="#">logical</a> indicating whether to calculate the Water.Loss. If it is FALSE, Water.Before, Water.After and Water.Amount will not be in the returned <a href="#">data.frame</a> . They can be copied across by listing them in a component of traits and set the corresponding component of cameras to NULL.
pixelsPERcm	A <a href="#">numeric</a> giving the number of pixels per cm for the images. <i>No longer used.</i>

### Details

The columns are copied from data, except for those columns in the list under **Value** that have '(calculated)' appended.

### Value

A [data.frame](#) containing the columns specified by cartId, imageTimes, timeAfterStart, idcolumns, traits and cameras. The defaults will result in the following columns:

1. Smarthouse: factor with levels for the Smarthouse
2. Lane: factor for lane number in a smarthouse
3. Position: factor for east/west position in a lane
4. Days: factor for the number of Days After Planting (DAP)
5. cartId: unique code for each cart
6. imageTimes: time at which an image was taken in POSIXct format
7. Reps: factor indexing the replicates for each combination of the factors in idcolumns (calculated)
8. xPosn: numeric for the Positions within a Lane (calculated)
9. Hour: hour of the day, to 2 decimal places, at which the image was taken (calculated)
10. xDays: numeric for the DAP that is centred by subtracting the mean of the unique days (calculated)
11. idcolumns: the columns listed in idcolumns that have been converted to factors
12. Weight.Before: weight of the pot before watering (only if calcWaterLoss is TRUE)
13. Weight.After: weight of the pot after watering (only if calcWaterLoss is TRUE)
14. Water.Amount: the weight of the water added (= Water.After - Water.Before) (calculated)
15. Water.Loss: the difference between Weight.Before for the current imaging and the Weight.After for the previous imaging (calculated unless calcWaterLoss is FALSE)
16. Area: the Projected.Shoot.Area..pixels. divided by 1000 (calculated)
17. Area.SV1: the Projected.Shoot.Area from Side View 1 divided by 1000 (calculated)
18. Area.SV2: the Projected.Shoot.Area from Side View 2 divided by 1000 (calculated)
19. Area.TV: the Projected.Shoot.Area from Top View divided by 1000 (calculated)
20. Boundary.To.Area.Ratio.SV1
21. Boundary.To.Area.Ratio.SV2
22. Boundary.To.Area.Ratio.TV
23. Caliper.Length.SV1
24. Caliper.Length.SV2
25. Caliper.Length.TV
26. Compactness.SV1 from Side View 1
27. Compactness.SV2 from Side View 2
28. Compactness.TV: from Top View
29. Convex.Hull.Area.SV1: area of Side View 1 Convex Hull divided by 1000 (calculated)
30. Convex.Hull.Area.SV2: area of Side View 2 Convex Hull divided by 1000 (calculated)
31. Convex.Hull.TV: Convex.Hull.Area.TV divided by 1000 (calculated)
32. Center.Of.Mass.Y.SV1: Centre of Mass from Side View 1
33. Center.Of.Mass.Y.SV2: Centre of Mass from Side View 2
34. Max.Dist.Above.Horizon.Line.SV1: the Max.Dist.Above.Horizon.Line.SV1 converted to cm using pixelsPERcm (calculated)
35. Max.Dist.Above.Horizon.Line.SV2: the Max.Dist.Above.Horizon.Line.SV2 converted to cm using pixelsPERcm (calculated)

**Author(s)**

**Examples**

```

data(exampleData)
longiPrime.dat <- longitudinalPrime(data=raw.dat, smarthouse.lev=1)

longiPrime.dat <- longitudinalPrime(data=raw.dat, smarthouse.lev=1,
                                   traits = list(a = "Area", c = "Compactness"),
                                   labsCamerasViews = list(all = c("SV1", "SV2", "TV"),
                                                            t = "TV"))

longiPrime.dat <- longitudinalPrime(data=raw.dat, smarthouse.lev=1,
                                   traits = c("Area.SV1", "Area.SV2", "Area.TV",
                                             "Compactness.TV"),
                                   labsCamerasViews = NULL)

longiPrime.dat <- longitudinalPrime(data=raw.dat, smarthouse.lev=1,
                                   calcWaterLoss = FALSE,
                                   traits = list(img = c("Area", "Compactness"),
                                                H2O = c("Weight.Before", "Weight.After",
                                                       "Water.Amount")),
                                   labsCamerasViews = list(all = c("SV1", "SV2", "TV"),
                                                            H2O = NULL))

```

---

probeDF

*Compares, for a set of specified values of df, a response and the smooths of it, possibly along with growth rates calculated from the smooths*

---

**Description**

Takes a response and, for each individual, uses [splitSplines](#) to smooth its values for each individual using the degrees of freedom values in `df`. Provided `get.rates` is TRUE, both the Absolute Growth Rates (AGR) and the Relative Growth Rates (RGR) are calculated for each smooth, either using differences or first derivatives. A combination of the unsmoothed and smoothed values, as well as the AGR and RGR, can be plotted for each value in `df`. Note that the arguments that modify the plots apply to all plots that are produced. The handling of missing values is controlled via `na.x.action` and `na.y.action`

**Usage**

```

probeDF(data, response = "Area", xname="xDays", individuals="Snapshot.ID.Tag",
        na.x.action="exclude", na.y.action = "exclude",
        df, smoothing.scale = "identity", correctBoundaries = FALSE,
        get.rates = TRUE, rates.method="differences",
        times.factor = "Days", x = NULL, x.title = NULL,

```

```

facet.x = "Treatment.1", facet.y = "Smarthouse", labeller = NULL,
colour = "black", colour.column=NULL, colour.values=NULL, alpha = 0.1,
which.traits = c("response", "AGR", "RGR"),
which.plots = "smoothedonly",
deviations.boxplots = "none",
ggplotFuncs = NULL,
...)
```

## Arguments

<code>data</code>	A <a href="#">data.frame</a> containing the data.
<code>response</code>	A character specifying the response variable to be supplied to <a href="#">smooth.spline</a> and that is to be plotted on the y-axis.
<code>xname</code>	A <a href="#">character</a> giving the name of the <a href="#">numeric</a> that contains the values of the predictor variable to be supplied to <a href="#">smooth.spline</a> .
<code>individuals</code>	A <a href="#">character</a> giving the name(s) of the <a href="#">factor</a> (s) that define the subsets of the data for which each subset corresponds to the response values for an individual.
<code>na.x.action</code>	A character string that specifies the action to be taken when values of x are NA. The possible values are <code>fail</code> , <code>exclude</code> or <code>omit</code> . For <code>exclude</code> and <code>omit</code> , predictions and derivatives will only be obtained for nonmissing values of x. The difference between these two codes is that for <code>exclude</code> the returned <code>data.frame</code> will have as many rows as <code>data</code> , the missing values have been incorporated.
<code>na.y.action</code>	A character string that specifies the action to be taken when values of y, or the response, are NA. The possible values are <code>fail</code> , <code>exclude</code> , <code>omit</code> , <code>allx</code> , <code>trimx</code> , <code>ltrimx</code> or <code>rtrimx</code> . For all options, except <code>fail</code> , missing values in y will be removed before smoothing. For <code>exclude</code> and <code>omit</code> , predictions and derivatives will be obtained only for nonmissing values of x that do not have missing y values. Again, the difference between these two is that, only for <code>exclude</code> will the missing values be incorporated into the returned <code>data.frame</code> . For <code>allx</code> , predictions and derivatives will be obtained for all nonmissing x. For <code>trimx</code> , they will be obtained for all nonmissing x between the first and last nonmissing y values that have been ordered for x; for <code>ltrimx</code> and <code>utrimx</code> either the lower or upper missing y values, respectively, are trimmed.
<code>df</code>	A <a href="#">numeric</a> specifying the set of degrees of freedom to be probed.
<code>smoothing.scale</code>	A <a href="#">character</a> giving the scale on which smoothing is to be performed. The two possibilities are <code>"identity"</code> , for directly smoothing the observed response, and <code>"logarithmic"</code> , for smoothing the log-transformed response.
<code>correctBoundaries</code>	A <a href="#">logical</a> indicating whether the fitted spline values are to have the method of Huang (2001) applied to them to correct for estimation bias at the end-points. Note that if <code>rates.method</code> is set to <code>"derivatives"</code> then it is not possible to have <code>correctBoundaries</code> set to <code>TRUE</code> .
<code>get.rates</code>	A <a href="#">logical</a> specifying whether or not the growth rates (AGR and RGR) are to be computed and stored.

rates.method	A <a href="#">character</a> specifying the method to use in calculating the growth rates. The two possibilities are "differences" and "derivates".
times.factor	A <a href="#">character</a> giving the name of the column in data containing the factor for times at which the data was collected. Its levels will be used in calculating growth rates and should be numeric values stored as characters.
x	A <a href="#">character</a> giving the variable to be plotted on the x-axis. If x is NULL then xname is used.
x.title	Title for the x-axis. If NULL then set to times.factor.
facet.x	A <a href="#">data.frame</a> giving the variable to be used to form subsets to be plotted in separate columns of plots. Use "." if a split into columns is not wanted.
facet.y	A <a href="#">data.frame</a> giving the variable to be used to form subsets to be plotted in separate rows of plots. Use "." if a split into columns is not wanted.
labeller	A <a href="#">ggplot function</a> for labelling the facets of a plot produced using the <a href="#">ggplot</a> function. For more information see <a href="#">ggplot</a> .
colour	A <a href="#">character</a> specifying a single colour to use in drawing the lines for the profiles. If colouring according to the values of a variable is required then use colour.column.
colour.column	A <a href="#">character</a> giving the name of a column in data over whose values the colours of the lines are to be varied. The colours can be specified using colour.values.
colour.values	A <a href="#">character</a> vector specifying the values of the colours to use in drawing the lines for the profiles. If this is a named vector, then the values will be matched based on the names. If unnamed, values will be matched in order (usually alphabetical) with the limits of the scale.
alpha	A <a href="#">numeric</a> specifying the degrees of transparency to be used in plotting. It is a ratio in which the denominator specifies the number of points (or line) that must be overplotted to give a solid cover.
which.traits	A <a href="#">character</a> giving the traits that are to be produced. One or more of response, AGR and RGR. If all, all three traits are produced. The unsmoothed growth rates are not calculated if only smoothed plots are requested.
which.plots	A <a href="#">character</a> giving the plots that are to be produced. If none, no plots are produced. If smoothedonly, plots of the smoothed traits are plotted. If bothseparately, plots of the unsmoothed trait followed by the smoothed trait are produced for each trait. If compare, a combined plot of the unsmoothed trait and the smoothed trait is produced for each value of df.
deviations.boxplots	A <a href="#">character</a> specifying whether boxplots of the absolute and/or relative deviations of the values of a trait from their smoothed values are to be produced (observed - smoothed). If none, no plots are produced. The argument which.traits controls the traits for which boxplots are produced.
ggplotFuncs	A <a href="#">list</a> , each element of which contains the results of evaluating a <a href="#">ggplot</a> function. It is created by calling the <a href="#">list</a> function with a <a href="#">ggplot</a> function call for each element. Note that these functions are applied to all three plots produced.
...	allows passing of arguments to <a href="#">longiPlot</a> .

**Value**

A `data.frame` containing `individuals`, `times.factor`, `facet.x`, `facet.y`, `xname`, `response`, and, for each `df`, the smoothed response, the AGR and the RGR. It is returned invisibly. The names of the new data are constructed by joining elements separated by full stops (`.`). In all cases, the last element is the value of `df`. For the smoothed response, the other elements are `response` and `"smooth"`; for AGR and RGR, the other elements are the name of the smoothed response and either `"AGR"` or `"RGR"`.

        ggplotFuncs=vline)
```

---

PVA

*Selects a subset of variables using Principal Variable Analysis (PVA)*

---

**Description**

Principal Variable Analysis (PVA) (Cummings, 2007) selects a subset from a set of the variables such that the variables in the subset are as uncorrelated as possible, in an effort to ensure that all aspects of the variation in the data are covered.

**Usage**

```
PVA(responses, data, nvarselect = NULL, p.variance = 1, include = NULL,
    plot = TRUE, ...)
```

**Arguments**

<code>responses</code>	A <a href="#">character</a> giving the names of the columns in data from which the variables are to be selected.
<code>data</code>	A <a href="#">data.frame</a> containing the columns of variables from which the selection is to be made.
<code>nvarselect</code>	A <a href="#">numeric</a> specifying the number of variables to be selected, which includes those listed in <code>include</code> . If <code>nvarselect = 1</code> , as many variables are selected as is need to satisfy <code>p.variance</code> .

p.variance	A <a href="#">numeric</a> specifying the minimum proportion of the variance that the selected variables must account for,
include	A <a href="#">character</a> giving the names of the columns in data for the variables whose selection is mandatory.
plot	A <a href="#">logical</a> indicating whether a plot of the cumulative proportion of the variance explained is to be produced.
...	allows passing of arguments to other functions

### Details

The variable that is most correlated with the other variables is selected first for inclusion. The partial correlation for each of the remaining variables, given the first selected variable, is calculated and the most correlated of these variables is selected for inclusion next. Then the partial correlations are adjusted for the second included variable. This process is repeated until the specified criteria have been satisfied. The possibilities are:

1. the default (`nvarselect = NULL` and `p.variance = 1`), which selects all variables in increasing order of amount of information they provide;
2. to select exactly `nvarselect` variables;
3. to select just enough variables, up to a maximum of `nvarselect` variables, to explain at least  $p.variance * 100$  per cent of the total variance.

### Value

A [data.frame](#) giving the results of the variable selection. It will contain the columns `Variable`, `Selected`, `h.partial`, `Added.Proprn` and `Cumulative.Proprn`.

results <- PVA(responses, longi.dat, p.variance=0.9, plot = FALSE)
```

---

rcontrib	<i>Computes a measure of how correlated each variable in a set is with the other variable, conditional on a nominated subset of them</i>
----------	--

---

### Description

A measure of how correlated a variable is with those in a set is given by the square root of the sum of squares of the correlation coefficients between the variables and the other variables in the set (Cummings, 2007). Here, the partial correlation between the subset of the variables listed in `response` that are not listed in `include` is calculated from the partial correlation matrix for the subset, adjusting for those variables in `include`. This is useful for manually deciding which of the variables not in `include` should next be added to it.

### Usage

```
rcontrib(responses, data, include = NULL)
```

### Arguments

<code>responses</code>	A <a href="#">character</a> giving the names of the columns in <code>data</code> from which the correlation measure is to be calculated.
<code>data</code>	A <a href="#">data.frame</a> containing the columns of variables from which the correlation measure is to be calculated.
<code>include</code>	A <a href="#">character</a> giving the names of the columns in <code>data</code> for the variables for which other variables are to be adjusted.

### Value

A [numeric](#) giving the correlation measures.

RiceRaw.dat

*Data for an experiment to investigate a rice germplasm panel***Description**

The data is from an experiment in a Smarthouse in the Plant Accelerator. It is described in Al-Tamimi et al. (2016). It is used in [imageData-package](#) as an executable example to illustrate the use of `imageData`.

**Usage**

```
data(RiceRaw.dat)
```

**Format**

A data.frame containing 14784 observations on 33 variables.

**Source**

It will be made available on Dryad

**References**

Al-Tamimi, N, Brien, C.J., Oakey, H., Berger, B., Saade, S., Ho, Y. S., Schmockel, S. M., Tester, M. and Negrao, S. (2016) New salinity tolerance loci revealed in rice using high-throughput non-invasive phenotyping. *Nature Communications*, **7**, 13342.

splitContGRdiff

*Adds the growth rates calculated continuously over time for subsets of a response to a data.frame***Description**

Uses [AGRdiff](#), [PGR](#) and [RGRdiff](#) to calculate growth rates continuously over time for a subset of the values of response and stores the results in data. The subsets are those values with the same levels combinations of the factors listed in INDICES.

**Usage**

```
splitContGRdiff(data, responses, INDICES,
  which.rates = c("AGR", "PGR", "RGR"), suffices.rates=NULL,
  times.factor = "Days")
```

**Arguments**

data	A <a href="#">data.frame</a> containing the columns for which growth rates are to be calculated.
responses	A <a href="#">character</a> giving the names of the columns in data for which growth rates are to be calculated.
INDICES	A <a href="#">character</a> giving the name(s) of the <a href="#">factor</a> (s) that define the subsets of response for which growth rates are to be calculated continuously. If the columns corresponding to INDICES are not <a href="#">factor</a> (s) then they will be coerced to <a href="#">factor</a> (s). The subsets are formed using <a href="#">by</a> .
which.rates	A <a href="#">character</a> giving the growth rates that are to be calculated. It should be a combination "AGR", "PGR" and "RGR".
times.factor	A <a href="#">character</a> giving the name of the column in data containing the factor for times at which the data was collected. Its levels will be used in calculating growth rates and should be numeric values stored as characters.
suffices.rates	A <a href="#">character</a> giving the characters to be appended to the names of the responses to provide the names of the columns containing the calculated growth rates. The order of the suffices in <code>suffices.rates</code> should correspond to the order of the elements of <code>which.rates</code> . If NULL, the values of <code>which.rates</code> are used.

**Value**

A [data.frame](#) containing data to which has been added a column for the differences between the `times.factor`, if it is not already in data, and columns with growth rates. The name of the column for `times.factor` differences will be the `times.factor` with ".diff" appended and, for each of the growth-rate columns will be the value of response with one of ".AGR", ".PGR" or "RGR" or the corresponding value from `suffices.GR` appended.

**Author(s)**

Chris Brien

**See Also**

[fitSpline](#), [splitSplines](#)

**Examples**

```
data(exampleData)
longi.dat <- splitContGRdiff(longi.dat, response="Area.smooth",
  INDICES = "Snapshot.ID.Tag", which.rates=c("AGR", "RGR"))
```

---

splitSplines	<i>Adds the fits after fitting a natural cubic smoothing spline to subsets of a response to a data.frame</i>
--------------	--

---

### Description

Uses `fitSpline` to fit a spline to a subset of the values of response and stores the fitted values in data. The subsets are those values with the same levels combinations of the factors listed in INDICES and the degrees of smoothing is controlled by df. The derivatives of the fitted spline can also be obtained, as can the Relative Growth Rates (RGR).

By default, `smooth.spline` will issue an error if there are not at least four distinct x-values. On the other hand, `fitSpline` issues a warning and sets all smoothed values and derivatives to NA. The handling of missing values in the observations is controlled via `na.x.action` and `na.y.action`.

### Usage

```
splitSplines(data, response, x, INDICES, df = NULL, smoothing.scale = "identity",
             correctBoundaries = FALSE,
             deriv = NULL, suffices.deriv=NULL, RGR=NULL, AGR=NULL, sep=".",
             na.x.action="exclude", na.y.action = "exclude", ...)
```

### Arguments

data	A <a href="#">data.frame</a> containing the column to be smoothed.
response	A <a href="#">character</a> giving the name of the column in data that is to be smoothed.
x	A <a href="#">character</a> giving the name of the column in data that contains the values of the predictor variable.
INDICES	A <a href="#">character</a> giving the name(s) of the <a href="#">factor</a> (s) that define the subsets of response that are to be smoothed separately. If the columns corresponding to INDICES are not <a href="#">factor</a> (s) then they will be coerced to <a href="#">factor</a> (s). The subsets are formed using <a href="#">split</a> .
df	A <a href="#">numeric</a> specifying the desired equivalent number of degrees of freedom of the smooth (trace of the smoother matrix). Lower values result in more smoothing. If df = NULL, ordinary leave-one-out cross-validation is used to determine the amount of smooth.
smoothing.scale	A <a href="#">character</a> giving the scale on which smoothing is to be performed. The two possibilities are "identity", for directly smoothing the observed response, and "logarithmic", for scaling the log-transformed response.
correctBoundaries	A <a href="#">logical</a> indicating whether the fitted spline values are to have the method of Huang (2001) applied to them to correct for estimation bias at the end-points. Note that deriv must be NULL for correctBoundaries to be set to TRUE.
deriv	A <a href="#">numeric</a> specifying one or more orders of derivatives that are required.

suffices.deriv	A <b>character</b> giving the characters to be appended to the names of the derivatives.
RGR	A <b>character</b> giving the character to be appended to the smoothed response to create the RGR name, but only when <code>smoothing.scale</code> is <code>identity</code> . When <code>smoothing.scale</code> is <code>identity</code> : (i) if RGR is not NULL deriv must include 1 so that the first derivative is available for calculating the RGR; (ii) if RGR is NULL, the RGR is not calculated from the AGR. When <code>smoothing.scale</code> is <code>logarithmic</code> , the RGR is the backtransformed first derivative and so, to obtain it, merely include 1 in deriv and any suffix for it in <code>suffices.deriv</code> .
AGR	A <b>character</b> giving the character to be appended to the smoothed response to create the AGR name, but only when <code>smoothing.scale</code> is <code>logarithmic</code> . When <code>smoothing.scale</code> is <code>logarithmic</code> : (i) if AGR is not NULL, deriv must include 1 so that the first derivative is available for calculating the AGR; (ii) If AGR is NULL, the AGR is not calculated from the RGR. When <code>smoothing.scale</code> is <code>identity</code> , the AGR is the first derivative and so, to obtain it, merely include 1 in deriv and any suffix for it in <code>suffices.deriv</code> .
sep	A <b>character</b> giving the separator to use when the levels of INDICES are combined. This is needed to avoid using a <b>character</b> that occurs in a factor to delimit levels when the levels of INDICES are combined to identify subsets.
na.x.action	A <b>character</b> string that specifies the action to be taken when values of x are NA. The possible values are <code>fail</code> , <code>exclude</code> or <code>omit</code> . For <code>exclude</code> and <code>omit</code> , predictions and derivatives will only be obtained for nonmissing values of x. The difference between these two codes is that for <code>exclude</code> the returned <code>data.frame</code> will have as many rows as <code>data</code> , the missing values have been incorporated.
na.y.action	A <b>character</b> string that specifies the action to be taken when values of y, or the response, are NA. The possible values are <code>fail</code> , <code>exclude</code> , <code>omit</code> , <code>allx</code> , <code>trimx</code> , <code>ltrimx</code> or <code>rtrimx</code> . For all options, except <code>fail</code> , missing values in y will be removed before smoothing. For <code>exclude</code> and <code>omit</code> , predictions and derivatives will be obtained only for nonmissing values of x that do not have missing y values. Again, the difference between these two is that, only for <code>exclude</code> will the missing values be incorporated into the returned <code>data.frame</code> . For <code>allx</code> , predictions and derivatives will be obtained for all nonmissing x. For <code>trimx</code> , they will be obtained for all nonmissing x between the first and last nonmissing y values that have been ordered for x; for <code>ltrimx</code> and <code>utrimx</code> either the lower or upper missing y values, respectively, are trimmed.
...	allows for arguments to be passed to <code>smooth.spline</code> .

### Value

A **data.frame** containing data to which has been added a column with the fitted smooth, the name of the column being `response` with `.smooth` appended to it. If `deriv` is not NULL, columns containing the values of the derivative(s) will be added to `data`; the name each of these columns will be the value of `response` with `.smooth.dvf` appended, where `f` is the order of the derivative, or the value of `response` with `.smooth.` and the corresponding element of `suffices.deriv` appended. If RGR is not NULL, the RGR is calculated as the ratio of value of the first derivative of the fitted spline and the fitted value for the spline. Any pre-existing smoothed and derivative columns in `data` will be replaced. The ordering of the `data.frame` for the x values will be preserved as far as is possible;

the main difficulty is with the handling of missing values by the function merge. Thus, if missing values in `x` are retained, they will occur at the bottom of each subset of INDICES and the order will be problematic when there are missing values in `y` and `na.y.action` is set to `omit`.

### Examples

```
data(exampleData)
longi.dat <- splitSplines(longi.dat, response="Area", x="xDays",
                          INDICES = "Snapshot.ID.Tag",
                          df = 4, deriv=1, suffices.deriv="AGRdv", RGR="RGRdv")
```

---

splitValueCalculate	<i>Calculates a single value that is a function of an individual's values for a response</i>
---------------------	--

---

### Description

Splits the values of a response into subsets corresponding individuals and applies a function that calculates a single value to each individual's observations. It includes the ability to calculate the observation that corresponds to the calculated value of the function.

### Usage

```
splitValueCalculate(response, weights=NULL, individuals = "Snapshot.ID.Tag",
                    FUN = "max", which.obs = FALSE, which.levels = NULL,
                    data, na.rm=TRUE, sep=".", ...)
```

### Arguments

response	A <a href="#">character</a> giving the name of the column in data from which the values of FUN are to be calculated.
weights	A <a href="#">character</a> giving the name of the column in data containing the weights to be supplied as <code>w</code> to FUN.
individuals	A <a href="#">character</a> giving the name(s) of the factor(s) that define the subsets of the data for which each subset corresponds to the response value for an individual.

FUN	A <a href="#">character</a> giving the name of the function that calculates the value for each subset.
which.obs	A <a href="#">logical</a> indicating whether or not to determine the observation corresponding to the value of the function, instead of the value of the function itself.
which.levels	A <a href="#">character</a> giving the name of the <a href="#">factor</a> whose levels are to be identified as the level of the observation whose value matches the value of the function.
data	A <a href="#">data.frame</a> containing the column from which the function is to be calculated.
na.rm	A <a href="#">logical</a> indicating whether NA values should be stripped before the calculation proceeds.
sep	A <a href="#">character</a> giving the separator to use when the levels of individuals are combined. This is needed to avoid using a <a href="#">character</a> that occurs in a factor to delimit levels when the levels of individuals are combined to identify subsets.
...	allows for arguments to be passed to FUN.

**Value**

A [data.frame](#), with the same number of rows as there are individuals, containing the values of the function for the individuals.

**Author(s)**

Chris Brien

**See Also**

[splitContGRdiff](#), [splitSplines](#)

**Examples**

```
data(exampleData)
Area.smooth.max <- splitValueCalculate("Area.smooth", data = longi.dat)
```

---

twoLevelOpcreate	<i>Creates a data.frame formed by applying, for each response, a binary operation to the paired values of two different treatments</i>
------------------	--

---

**Description**

Takes pairs of values for a set of responses indexed by a two-level `treatment.factor` and calculates, for each of pair, the result of applying a binary operation to their values for the two levels of the `treatment.factor`. The level of the `treatment.factor` designated the control will be on the right of the binary operator and the value for the other level will be on the left.

**Usage**

```
twoLevelOpcreate(responses, data, treatment.factor = "Treatment.1",
  suffices.treatment = c("Cont", "Salt"), control = 1,
  columns.suffixed = NULL,
  operations = "/", suffices.results="OST",
  columns.retained = c("Snapshot.ID.Tag", "Smarthouse", "Lane",
    "Zones", "xZones", "SHZones", "ZLane",
    "ZMainplots", "xMainPosn", "Genotype.ID"),
  by = c("Smarthouse", "Zones", "ZMainplots"))
```

**Arguments**

- responses** A [character](#) giving the names of the columns in data that contain the responses to which the binary operations are to be applied.
- data** A [data.frame](#) containing the columns specified by `treatment.factor`, `columns.retained` and `responses`.
- treatment.factor** A [factor](#) with two levels corresponding to what is to be designated the control and treated observations .
- suffices.treatment** A [character](#) giving the characters to be appended to the names of the responses and `columns.suffixed` in constructing the names of the columns containing the responses and `columns.suffixed` for each level of the `treatment.factor`. The order of the suffices in `suffices.treatment` should correspond to the order of the levels of `treatment.factor`.
- control** A [numeric](#), equal to either 1 or 2, that specifies the level of `treatment.factor` that is the control treatment. The value for the control level will be on the right of the binary operator.
- columns.suffixed** A [character](#) giving the names of the `columns.retained` in data that are to be have the values for each treatment retained and whose names are to be suffixed using `suffices.treatment`. Generally, this is done when `columns.retained` has different values for different levels of the `treatment.factor`.
- operations** A [character](#) giving the binary operations to perform on the values for the two different levels of the `treatment.factor`. It should be either of length one, in which case the same operation will be performed for all columns specified in `response.GR`, or equal in length to `response.GR` so its elements correspond to those of `response.GR`.
- suffices.results** A [character](#) giving the characters to be appended to the names of the responses in constructing the names of the columns containing the results of applying the operations. The order of the suffices in `suffices.results` should correspond to the order of the operators in `operations`.
- columns.retained** A [character](#) giving the names of the columns in data that are to be retained in the `data.frame` being created. These are usually [factors](#) that index the results of applying the operations and that might be used subsequently.

by A **character** giving the names of the columns in data whose combinations will be unique for the observation for each treatment. It is used by `merge` when combining the values of the two treatments in separate columns in the `data.frame` to be returned.

### Value

A `data.frame` containing the following columns and the values of the :

1. those from data nominated in `columns.retained`;
2. those containing the treated values of the columns whose names are specified in `responses`; the treated values are those having the other level of `treatment.factor` to that specified by `control`;
3. those containing the control values of the columns whose names are specified in `responses`; the control values are those having the level of `treatment.factor` specified by `control`;
4. those containing the values calculated using the binary operations; the names of these columns will be constructed from `responses` by appending `suffices.results` to them.

### Author(s)

Chris Brien

### Examples

```
data(exampleData)
responses <- c("Area.smooth.AGR", "Area.smooth.RGR")
cols.retained <- c("Snapshot.ID.Tag", "Smarthouse", "Lane", "Position",
                  "Days", "Snapshot.Time.Stamp", "Hour", "xDays",
                  "Zones", "xZones", "SHZones", "ZLane", "ZMainplots",
                  "xMainPosn", "Genotype.ID")
longi.SIIT.dat <-
  twoLevelOpcreate(responses, longi.dat, suffices.treatment=c("C", "S"),
                  operations = c("-", "/"),
                  suffices.results = c("diff", "SIIT"),
                  columns.retained = cols.retained,
                  by = c("Smarthouse", "Zones", "ZMainplots", "Days"))
longi.SIIT.dat <- with(longi.SIIT.dat,
                      longi.SIIT.dat[order(Smarthouse, Zones, ZMainplots, Days),])
```

---

WUI

*Calculates the Water Use Index (WUI)*

---

### Description

Calculates the Water Use Index, returning NA if the water use is zero.

### Usage

```
WUI(response, water)
```

**Arguments**

response      A *numeric* giving the value of the response achieved.  
water          A *numeric* giving the amount of water used.

**Value**

A *numeric* containing the water divided by the response, unless water is zero in which case NA is returned.

**Author(s)**

Chris Brien

**Examples**

```
data(exampleData)  
Area.WUE <- with(longi.dat, WUI(Area.AGR, Water.Loss))
```
